

ORF 201
COMPUTER METHODS FOR PROBLEM SOLVING

Lecture 13
Linked Lists (Jotto)

“The secret to happiness is: Always get as much RAM as you can possibly afford.”

The Game Jotto

Pick a 5-letter word: *teach*

Your opponent queries 5-letter words.

To each, you respond with number of "matches":

Query	Matches
<i>baste</i>	3
<i>ledge</i>	1
<i>abode</i>	2
<i>tepid</i>	2
<i>metro</i>	2
<i>lathe</i>	4

Game ends when number of matches is 5. That is, when query either matches hidden word exactly or is an anagram of it.

Humans Opponents Use Logic

Query	Matches
<i>baste</i>	3
<i>ledge</i>	1
<i>abode</i>	2
<i>tepid</i>	2
<i>metro</i>	2
<i>lathe</i>	4

Let's see, *lathe* has 4 matches. Therefore, *a* and *e* are either both in or only one of them is in. Suppose first that both are in. Then, from *baste*, *b*, *s*, and *t* are out. From *ledge*, *l*, *d*, and *g* are out. From *abode*, *o* is out too. Etc.

Now, suppose that *a* is in but *e* is out. Then from *lathe*, *l*, *t*, and *h* are out too. Etc.

Computer Algorithm for Jotto

- (1) Read a list of all 5-letter words (there are 2415).
- (2) Pick a word at random from the list as the first query.
- (3) After being told the number of matches, strike from the list every word that fails to produce that response.
- (4) Go back to step 2.

Here's a sample output from computer Jotto:

```
Think of a 5-letter word
Are you ready to begin (y/n)? y

There are 2415 words in my dictionary.
My 1-th guess is: gorge
How many matches? 1

There are 1046 words in my dictionary.
My 2-th guess is: lathe
How many matches? 4

There are 39 words in my dictionary.
My 3-th guess is: slate
How many matches? 3

There are 16 words in my dictionary.
My 4-th guess is: ethyl
How many matches? 3
```

Main

```
public static void main(String[] args)
{
    int m;
    String guess;
    readDictionary();
    System.out.println("Think of a 5-letter word");

    for (int k=1; ; k++) {
        System.out.println();
        System.out.println("There are " +n+
                           " words in my dictionary");
        if (n==0) {
            System.out.println("Sorry, your word is "+
                               "not in my dictionary");
            break;
        }
        guess = pickRandom();
        System.out.println("My "+k+"-th guess is: "+guess);
        m = Console.in.readInt("How many matches? ");
        if (m==5) {
            System.out.println("I win, I win!");
            break;
        }
        if (m>5 || m<0) {
            System.out.println("No Way! Try again.");
            continue;
        }
        removeWords(m, guess);
    }
}
```

Store Dictionary in a Linked List

```
class WordLink
{
    String word;
    WordLink next;
}

public class Jotto
{
    /* Class variables */

    static int n;           // size of dictionary
    static WordLink firstWord; // Pointer to first word
                             // in linked list

    .
    .
    .
}
```

firstword

readDictionary ()

```
static void readDictionary()
{
    BufferedReader in;
    try{
        in = new BufferedReader(new FileReader("words5"));
    }
    catch (FileNotFoundException fe) {
        System.err.println("File not found");
        return;
    }

    String word;

    firstWord = null;
    n = 0;
    while (true) {
        word = FileIO.readString(in);
        if (word == null) {break;} // End of file
        addWord(word);
    }
}
```

null is a Java language word.
It is a pointer to nowhere.

addWord()

```
static void addWord(String word)
{
    WordLink newlink;

    newlink = new WordLink();
    newlink.word = word;
    newlink.next = firstWord;
    firstWord = newlink;
    n++;
}
```

removeWords() and deleteNextWord()

```
static void removeWords(int m, String guess)
{
    WordLink curr, prev;
    prev = null;
    for (curr = firstWord; curr != null; curr = curr.next) {
        if nmatches(guess, curr.word) != m) {
            deleteNextWord(prev);
        } else {
            prev = curr;
        }
    }
}
```

```
static void deleteNextWord(WordLink prev)
{
    if (prev == null) {
        firstWord = firstWord.next;
    } else {
        prev.next = prev.next.next;
    }
    n--;
}
```

pickRandom()

```
static String pickRandom()
{
    WordLink curr;
    int j = (int) (n*Math.random());

    for (curr=firstWord; curr!=null; curr=curr.next) {
        if (j<=0) break;
        j--;
    }

    return curr.word;
}
```

Note the **for** loop paradigm
for linked lists.

nmatches()

```
static int nmatches(String s1, String s2)
{
    int i, j;
    int len1 = s1.length();
    int len2 = s2.length();
    int cnt = 0;
    char[] c1 = new char[len1];
    char[] c2 = new char[len2];
    int[] f = new int[len2];

    s1.getChars(0, len1, c1, 0);
    s2.getChars(0, len2, c2, 0);

    for (j=0; j<len2; j++) { f[j]=0; }

    for (i=0; i<len1; i++) {
        for (j=0; j<len2; j++) {
            if (c2[i] == c1[j] && f[j] == 0) {
                f[j] = 1;
                break; // out of the for(j...) loop
            }
        }
    }
    for (j=0; j<len2; j++) {cnt += f[j]; }
    return cnt;
}
```
