# Degeneracy

## Definitions.

A *dictionary* is *degenerate* if one or more “rhs”-value vanishes.

Example:

$$\begin{array}{r} \zeta = 6 + w_3 + 5x_2 + 4w_1 \\ \hline x_3 = 1 - 2w_3 - 2x_2 + 3w_1 \\ w_2 = 4 + w_3 + x_2 - 3w_1 \\ x_1 = 3 - 2w_3 \\ w_4 = 2 + w_3 - w_1 \\ w_5 = 0 - x_2 + w_1 \end{array}$$

A *pivot* is *degenerate* if the objective function value does not change.

Examples (based on above dictionary):

1. If  $x_2$  enters, then  $w_5$  must leave, pivot is degenerate.
2. If  $w_1$  enters, then  $w_2$  must leave, pivot is *not* degenerate.

*Definition.* A *cycle* is a sequence of pivots that returns to the first dictionary in the sequence.

Note: Every pivot in a cycle must be degenerate. Why?

## Pivot Rules.

*Definition.* A *pivot rule* is an explicit statement for how one chooses entering and leaving variables (when a choice exists).

*Largest-Coefficient Rule.* A common pivot rule for entering variable:

Choose the variable with the largest coefficient in the objective function.

*Hope.*  
Some pivot rule, such as the largest coefficient rule, will be proven never to cycle.

# Hope Fades

An example that cycles using the following pivot rules:

- entering variable: largest-coefficient rule.
- leaving variable: smallest-index rule.

$$\begin{array}{rcl} \zeta & = & x_1 - 2x_2 - 2x_4 \\ \hline w_1 & = & -0.5x_1 + 3.5x_2 + 2x_3 - 4x_4 \\ w_2 & = & -0.5x_1 + x_2 + 0.5x_3 - 0.5x_4 \\ w_3 & = & 1 - x_1 . \end{array}$$

Here's a demo of cycling (ignoring the last constraint)...

**Current Dictionary**

$$\begin{array}{l} \text{obj} = 0 + 1 x_1 + (-2) x_2 + 0 x_3 + (-2) x_4 \\ w_1 = 0 - 1/2 x_1 - (-7/2) x_2 - (-2) x_3 - 4 x_4 \\ w_2 = 0 - 1/2 x_1 - (-1) x_2 - (-1/2) x_3 - 1/2 x_4 \end{array}$$

$x_1 \Leftrightarrow w_1$ :

**Current Dictionary**

$$\begin{array}{l} \text{obj} = 0 + (-2) w_1 + 5 x_2 + 4 x_3 + (-10) x_4 \\ x_1 = 0 - 2 w_1 - (-7) x_2 - (-4) x_3 - 8 x_4 \\ w_2 = 0 - (-1) w_1 - 5/2 x_2 - 3/2 x_3 - (-7/2) x_4 \end{array}$$

$x_2 \Leftrightarrow w_2$ :

**Current Dictionary**

$$\begin{array}{l} \text{obj} = 0 + 0 w_1 + (-2) w_2 + 1 x_3 + (-3) x_4 \\ x_1 = 0 - (-4/5) w_1 - 14/5 w_2 - 1/5 x_3 - (-9/5) x_4 \\ x_2 = 0 - (-2/5) w_1 - 2/5 w_2 - 3/5 x_3 - (-7/5) x_4 \end{array}$$

$x_3 \Leftrightarrow x_1$ :

**Current Dictionary**

$$\begin{array}{l} \text{obj} = 0 + 4 w_1 + (-16) w_2 + (-5) x_1 + 6 x_4 \\ x_3 = 0 - (-4) w_1 - 14 w_2 - 5 x_1 - (-9) x_4 \\ x_2 = 0 - 2 w_1 - (-8) w_2 - (-3) x_1 - 4 x_4 \end{array}$$

$x_4 \Leftrightarrow x_2$ :

Current Dictionary													
obj =	0	+	1	w1	+	-4	w2	+	-1/2	x1	+	-3/2	x2
x3 =	0	-	1/2	w1	-	-4	w2	-	-7/4	x1	-	9/4	x2
x4 =	0	-	1/2	w1	-	-2	w2	-	-3/4	x1	-	1/4	x2

$w_1 \Leftrightarrow x_3$ :

Current Dictionary													
obj =	0	+	-2	x3	+	4	w2	+	3	x1	+	-6	x2
w1 =	0	-	2	x3	-	-8	w2	-	-7/2	x1	-	9/2	x2
x4 =	0	-	-1	x3	-	2	w2	-	1	x1	-	-2	x2

$w_2 \Leftrightarrow x_4$ :

Current Dictionary													
obj =	0	+	0	x3	+	-2	x4	+	1	x1	+	-2	x2
w1 =	0	-	-2	x3	-	4	x4	-	1/2	x1	-	-7/2	x2
w2 =	0	-	-1/2	x3	-	1/2	x4	-	1/2	x1	-	-1	x2

*Cycling is rare!* A program that generates random  $2 \times 4$  fully degenerate problems was run more than *one billion* times and did not find one example!

# Perturbation Method

Whenever a vanishing “rhs” appears perturb it.  
If there are lots of them, say  $k$ , perturb them all.  
Make the perturbations at different *scales*:

$$\text{other nonzero data} \gg \epsilon_1 \gg \epsilon_2 \gg \dots \gg \epsilon_k > 0.$$

*An Example.*

		Current Dictionary															
obj	=	0.0	+	0.0	e1	+	0.0	e2	+	0.0	e3	+	2.0	x1	+	4.0	x2
w1	=	0.0	+	1.0	e1	+	0.0	e2	+	0.0	e3	-	-1.0	x1	-	1.0	x2
w2	=	0.0	+	0.0	e1	+	1.0	e2	+	0.0	e3	-	-3.0	x1	-	1.0	x2
w3	=	0.0	+	0.0	e1	+	0.0	e2	+	1.0	e3	-	4.0	x1	-	-1.0	x2

Entering variable:  $x_2$

Leaving variable:  $w_2$

		Current Dictionary															
obj	=	0.0	+	0.0	e1	+	4.0	e2	+	0.0	e3	+	14.0	x1	+	-4.0	w2
w1	=	0.0	+	1.0	e1	+	-1.0	e2	+	0.0	e3	-	2.0	x1	-	-1.0	w2
x2	=	0.0	+	0.0	e1	+	1.0	e2	+	0.0	e3	-	-3.0	x1	-	1.0	w2
w3	=	0.0	+	0.0	e1	+	1.0	e2	+	1.0	e3	-	1.0	x1	-	1.0	w2

## Perturbation Method—Example Con't.

Recall current dictionary:

		Current Dictionary															
obj	=	0.0	+	0.0	e1	+	4.0	e2	+	0.0	e3	+	14.0	x1	+	-4.0	w2
w1	=	0.0	+	1.0	e1	+	-1.0	e2	+	0.0	e3	-	2.0	x1	-	-1.0	w2
x2	=	0.0	+	0.0	e1	+	1.0	e2	+	0.0	e3	-	-3.0	x1	-	1.0	w2
w3	=	0.0	+	0.0	e1	+	1.0	e2	+	1.0	e3	-	1.0	x1	-	1.0	w2

Entering variable:  $x_1$

Leaving variable:  $w_3$

		Current Dictionary															
obj	=	0.0	+	0.0	e1	+	18.0	e2	+	14.0	e3	+	-14.0	w3	+	-18.0	w2
w1	=	0.0	+	1.0	e1	+	-3.0	e2	+	-2.0	e3	-	-2.0	w3	-	-3.0	w2
x2	=	0.0	+	0.0	e1	+	4.0	e2	+	3.0	e3	-	3.0	w3	-	4.0	w2
x1	=	0.0	+	0.0	e1	+	1.0	e2	+	1.0	e3	-	1.0	w3	-	1.0	w2

# Other Pivot Rules

## *Smallest Index Rule.*

Choose the variable with the smallest index (the  $x$  variables are assumed to be “before” the  $w$  variables).

Note: Also known as *Bland's rule*.

## *Random Selection Rule.*

Select at random from the set of possibilities.

## *Greatest Increase Rule.*

Pick the entering/leaving pair so as to maximize the increase of the objective function over all other possibilities.

Note: Too much computation.

*Cycling Theorem.* If the simplex method fails to terminate, then it must cycle.

Why?

*Fundamental Theorem of Linear Programming.* For an arbitrary linear program in standard form, the following statements are true:

1. If there is no optimal solution, then the problem is either infeasible or unbounded.
2. If a feasible solution exists, then a basic feasible solution exists.
3. If an optimal solution exists, then a basic optimal solution exists.

# Geometry

$$\begin{array}{ll} \text{maximize} & x_1 + 2x_2 + 3x_3 \\ \text{subject to} & x_1 + 2x_3 \leq 3 \\ & x_2 + 2x_3 \leq 2 \\ & x_1, x_2, x_3 \geq 0. \end{array}$$

$$\begin{array}{ll} \text{maximize} & x_1 + 2x_2 + 3x_3 \\ \text{subject to} & x_1 + 2x_3 \leq 2 \\ & x_2 + 2x_3 \leq 2 \\ & x_1, x_2, x_3 \geq 0. \end{array}$$
