Objective

Create a system Point Spread Function (PSF) with the needed *contrast* allowing planet discovery at the smallest *inner working distance* (*IWD*) in the shortest *integration time*.

Outline

- Point Spread Function for Equal-Area Apertures
- Performance Metrics
- Apodized Pupils Comparisons
- Optimal Shaped Pupil Designs

Note: We assume systematic error is separately reduced to below background.

[Home Page](#)[Title Page](#)[Contents](#)[Page 2 of 20](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

Background

Irradiance $I(\xi, \zeta)$ is an intensity I_o times the point spread function $P(\xi, \zeta)$:

$$I(\xi, \zeta) = I_o P(\xi, \zeta)$$

The intensity I_o depends only on the source strength and the aperture area $A = a^2$.

The point spread function (PSF) for a $a\sqrt{r} \times a/\sqrt{r}$ rectangular design space is given by

$$P(\xi, \zeta) = \left| \int_{-\frac{1}{2\sqrt{r}}}^{\frac{1}{2\sqrt{r}}} \int_{-\frac{\sqrt{r}}{2}}^{\frac{\sqrt{r}}{2}} \mathcal{A}(y, z) e^{-2\pi i(\xi y + \zeta z)} dy dz \right|^2,$$

where the function $\mathcal{A}()$ denotes the apodization function.

We distinguish purely open/closed pupils from smooth apodizations:

$$\begin{aligned} \mathcal{A} \in \{0, 1\} &\implies \textit{pupil mask} \\ \mathcal{A} \in [0, 1] &\implies \textit{smooth apodization.} \end{aligned}$$

[Home Page](#)[Title Page](#)[Contents](#)[Page 3 of 20](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

Optimization Criteria

We compare and optimize different designs with equal pre-apodized aperture area.

Comparisons are made on four performance metrics:

- Contrast
- Integration Time
- Inner Working Distance
- Discovery Space

Contrast

Brown and Burrows (Icarus 1990) introduced the *contrast quotient*:

$$Q = \frac{I_{\text{planet}} P(0, 0)}{I_{\text{star}} P(\xi_{\text{planet}}, \zeta_{\text{planet}}) + I_{\text{scatter}}} = \frac{I_{\text{planet}} P(0, 0)}{I_{\text{bkgrd}}}$$

where I_{planet} denotes the planet's irradiance, I_{star} denotes the star's irradiance, and $(\xi_{\text{planet}}, \zeta_{\text{planet}})$ denotes the image-plane coordinates of the planet relative to an on-axis parent star.

It is estimated that $I_{\text{planet}}/I_{\text{star}}$ might be as small as 10^{-10} . Hence, to have a unit contrast ratio, $Q = 1$, we require

$$P(\xi_{\text{planet}}, \zeta_{\text{planet}}) \leq 10^{-10} P(0, 0).$$

Integration Time

Detection in Known Background

Assume Poisson arrival statistics for planet signal and background:

$$S/N = \frac{I_{\text{planet}} t \Delta P}{\sqrt{I_{\text{bkgrd}} t \Delta S}} \quad \Longrightarrow \quad t_1 = \frac{(S/N)^2 P(0,0) \Delta S}{I_{\text{planet}} Q \Delta P^2},$$

where ΔP denotes the area under the PSF in a neighborhood ΔS of $(0,0)$.

Photometry in Unknown Background (Characterization)

$$t_2 = \frac{(S/N)^2 P(0)}{I_{\text{planet}} [\Delta S \Delta^2 P - (\Delta P)^2]} \left\{ \frac{\Delta S^2 \Delta^3 P - (\Delta P)^3}{P(0,0) [\Delta S \Delta^2 P - (\Delta P)^2]} + \frac{\Delta S}{Q} \right\}$$

[Home Page](#)[Title Page](#)[Contents](#)[Page 6 of 20](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

Inner Working Distance (IWD)

The smallest angular separation from the star for which the PSF contrast reaches the required value of 10^{-10} .

Discovery Space

The azimuthal region of the image plane within which discovery is possible; that is, where 10^{-10} contrast is achieved.

Apodized Pupils

Apodized Square Aperture (ASA) (Nisenson & Papaliolios, ApJ 2001)

Left The PSF for an ASA with a sonine apodization ($\nu = 5$) plotted on a logarithmic scale with black areas 10^{-10} below brightest. *Right* Cross section of ASA on diagonal showing inner working distance of $5\lambda/a$. Single-exposure integration time of $t_1 = 25.5$.

On-diagonal, $IWD \approx 5\lambda/a$. Single-exp. integration time of $t_1 = 9.5$.

Generalized Prolate Spheroidal (GPS) Apodization

Note: Circular Telescope

IWD = $3.5\lambda/a$. Single-exposure integration time of $t_1 = 17$.

Integration Times for Apodizations

<i>Type</i>	$\frac{t_1 I_p}{(S/N)^2}$	$\frac{t_2 I_p}{(S/N)^2}$	<i>IWD</i>	<i>Disc. Space</i>
Sonine, $\nu = 5$	25.5	48	5 (diag), 13 (axis)	$< 1/2$
Sonine, $\nu = 4$	19	35	7 (diag), 15 (axis)	$< 1/2$
1-D Prolate	9.5	16.5	5 (diag), 4 (axis)	$1/2$
Gen. Prolate	17	34	3.5	full

Integration time comparisons for four different pupil apodizations in equal area apertures. Integration times are for a single exposure and have been normalized by planet irradiance and signal-to-noise ratio. The integration time t_1 assumes a known background level and is for planet discovery only. The integration time t_2 simultaneously estimates planet and background irradiance by using a region of the image plane slightly larger than the full width of the main lobe.

Integration Times for Masks

<i>Type</i>	$\frac{t_1 I_p}{(S/N)^2}$	$\frac{t_2 I_p}{(S/N)^2}$	<i>IWD</i>	<i>Discovery Space</i>
single prolate	4.6	8	4	$\ll 1/2$
6 pupil rectangle	15	21	4.2	$1/2$
6 pupil ellipse small OWD	6.5	9.5	2.8	$1/4$
6 pupil ellipse large OWD	4.8	7	4.5	$1/4$
8 pupil Eclipse	7.9	11	3.5	$1/2$
Concentric Rings	18	25	3.5	<i>full</i>

Integration time comparisons for three different shaped pupil apodizations in equal area apertures. Integration times are for a single exposure and have been normalized by planet irradiance and signal-to-noise ratio. The integration time t_1 assumes a known background level and is for planet discovery only. The integration time t_2 simultaneously estimates planet and background irradiance by using a region of the image plane slightly larger than the full width of the main lobe.

Conclusions

SHAPED PUPIL MASKS RULE! Here's why:

- Better integration time, inner working distance, discovery space.
- Easier to manufacture.
- Less susceptibility to space environment.
- Flexible design.
 - On or off axis.
 - Discovery vs. characterization.
- Advantages of tailoring the PSF.
 - High PSF contrast implies high speckle contrast.
 - Insensitivity to jitter and stellar size.
- The best shaped pupils are as good as or better than the best graded apodizations.
